

Fast Computation of Bernoulli, Tangent and Secant Numbers

Richard P. Brent and David Harvey

Abstract We consider the computation of Bernoulli, Tangent (zag), and Secant (zig or Euler) numbers. In particular, we give asymptotically fast algorithms for computing the first n such numbers in $O(n^2(\log n)^{2+o(1)})$ bit-operations. We also give very short in-place algorithms for computing the first n Tangent or Secant numbers in $O(n^2)$ integer operations. These algorithms are extremely simple, and fast for moderate values of n . They are faster and use less space than the algorithms of Atkinson (for Tangent and Secant numbers) and Akiyama and Tanigawa (for Bernoulli numbers).

1 Introduction

The *Bernoulli numbers* are rational numbers B_n defined by the generating function

$$\sum_{n \geq 0} B_n \frac{z^n}{n!} = \frac{z}{\exp(z) - 1}. \quad (1)$$

Bernoulli numbers are of interest in number theory and are related to special values of the Riemann zeta function (see §2). They also occur as coefficients in the Euler-Maclaurin formula, so are relevant to high-precision computation of special functions [7, §4.5].

It is sometimes convenient to consider *scaled* Bernoulli numbers

$$C_n = \frac{B_{2n}}{(2n)!}, \quad (2)$$

with generating function

$$\sum_{n \geq 0} C_n z^{2n} = \frac{z/2}{\tanh(z/2)}. \quad (3)$$

The generating functions (1) and (3) only differ by the single term $B_1 z$, since the other odd terms vanish.

The *Tangent numbers* T_n , and *Secant numbers* S_n , are defined by

$$\sum_{n \geq 0} T_n \frac{z^{2n-1}}{(2n-1)!} = \tan z, \quad \sum_{n \geq 0} S_n \frac{z^{2n}}{(2n)!} = \sec z. \quad (4)$$

In this paper, which is based on an a talk given by the first author at a workshop held to mark Jonathan Borwein's sixtieth birthday, we consider some algorithms for computing Bernoulli, Tangent and Secant numbers. For background, combinatorial interpretations, and references, see Abramowitz and Stegun [1, Ch. 23] (where the notation differs from ours, e.g. $(-1)^n E_{2n}$ is used for our S_n), and Sloane's [29] sequences A000367, A000182, A000364.

Let $M(n)$ be the number of bit-operations required for n -bit integer multiplication. The Schönhage-Strassen algorithm [27] gives $M(n) = O(n \log n \log \log n)$, and Fürer [17] has recently given an improved bound $M(n) = O(n(\log n)2^{\log^* n})$. For simplicity we merely assume that $M(n) = O(n(\log n)^{1+o(1)})$, where the $o(1)$ term depends on the precise algorithm used for multiplication. For example, if the Schönhage-Strassen algorithm is used, then the $o(1)$ term can be replaced by $\log \log \log n / \log \log n$.

In §§2–3 we mention some relevant and generally well-known facts concerning Bernoulli, Tangent and Secant numbers.

Recently, Harvey [20] showed that the *single* number B_n can be computed in $O(n^2(\log n)^{2+o(1)})$ bit-operations using a modular algorithm. In this paper we show that *all* the Bernoulli numbers B_0, \dots, B_n can be computed with the same complexity bound (and similarly for Secant and Tangent numbers).

In §4 we give a relatively simple algorithm that achieves the slightly weaker bound $O(n^2(\log n)^{3+o(1)})$. In §5 we describe the improvement to $O(n^2(\log n)^{2+o(1)})$. The idea is similar to that espoused by Steel [31], although we reduce the problem to division rather than multiplication. It is an open question whether the *single* number B_{2n} can be computed in $o(n^2)$ bit-operations.

In §6 we give very short in-place algorithms for computing the first n Secant or Tangent numbers using $O(n^2)$ integer operations. These algorithms are extremely simple, and fast for moderate values of n (say $n \leq 1000$), although asymptotically not as fast as the algorithms given in §§4–5. Bernoulli numbers can easily be deduced from the corresponding Tangent numbers using the relation (14) below.

2 Bernoulli Numbers

From the generating function (1) it is easy to see that the B_n are rational numbers, with $B_{2n+1} = 0$ if $n > 0$. The first few nonzero B_n are: $B_0 = 1, B_1 = -1/2, B_2 = 1/6, B_4 = -1/30, B_6 = 1/42, B_8 = -1/30, B_{10} = 5/66, B_{12} = -691/2730, B_{14} = 7/6$.

The denominators of the Bernoulli numbers are given by the *Von Staudt – Clausen Theorem* [12, 30], which states that

$$B'_{2n} := B_{2n} + \sum_{(p-1)|2n} \frac{1}{p} \in \mathbb{Z}.$$

Here the sum is over all primes p for which $p - 1$ divides $2n$.

Since the “correction” $B'_{2n} - B_{2n}$ is easy to compute, it might be convenient in a program to store the integers B'_{2n} instead of the rational numbers B_{2n} or C_n .

Euler found that the Riemann zeta-function for even non-negative integer arguments can be expressed in terms of Bernoulli numbers – the relation is

$$(-1)^{n-1} \frac{B_{2n}}{(2n)!} = \frac{2\zeta(2n)}{(2\pi)^{2n}}. \quad (5)$$

Since $\zeta(2n) = 1 + O(4^{-n})$ as $n \rightarrow +\infty$, we see that

$$|B_{2n}| \sim \frac{2(2n)!}{(2\pi)^{2n}}.$$

From Stirling’s approximation to $(2n)!$, the number of bits in the integer part of B_{2n} is $2n \lg n + O(n)$ (we write \lg for \log_2). Thus, it takes $\Omega(n^2 \log n)$ space to store B_1, \dots, B_n . We can not expect any algorithm to compute B_1, \dots, B_n in fewer than $\Omega(n^2 \log n)$ bit-operations.

Another connection between the Bernoulli numbers and the Riemann zeta-function is the identity

$$\frac{B_{n+1}}{n+1} = -\zeta(-n) \quad (6)$$

for $n \in \mathbb{Z}, n \geq 1$. This follows from (5) and the functional equation for the zeta-function, or directly from a contour integral representation of the zeta-function [33].

From the generating function (1), multiplying both sides by $\exp(z) - 1$ and equating coefficients of z , we obtain the recurrence

$$\sum_{j=0}^k \binom{k+1}{j} B_j = 0 \text{ for } k > 0. \quad (7)$$

This recurrence has traditionally been used to compute B_0, \dots, B_{2n} with $O(n^2)$ arithmetic operations, for example in [22]. However, this is unsatisfactory if floating-point numbers are used, because the recurrence is *numerically unstable*: the relative

error in the computed B_{2n} is of order $4^n \varepsilon$ if the floating-point arithmetic has precision ε , i.e. $\lg(1/\varepsilon)$ bits.

Let C_n be defined by (2). Then, multiplying each side of (3) by $\sinh(z/2)/(z/2)$ and equating coefficients gives the recurrence

$$\sum_{j=0}^k \frac{C_j}{(2k+1-2j)! 4^{k-j}} = \frac{1}{(2k)! 4^k}. \quad (8)$$

Using this recurrence to evaluate C_0, C_1, \dots, C_n , the relative error in the computed C_n is only $O(n^2 \varepsilon)$, which is satisfactory from a numerical point of view.

Equation (5) can be used in several ways to compute Bernoulli numbers. If we want just one Bernoulli number B_{2n} then $\zeta(2n)$ on the right-hand-side of (5) can be evaluated to sufficient accuracy using the Euler product: this is the “zeta-function” algorithm for computing Bernoulli numbers mentioned (with several references to earlier work) by Harvey [20]. On the other hand, if we want several Bernoulli numbers, then we can use the generating function

$$\frac{\pi z}{\tanh(\pi z)} = -2 \sum_{k=0}^{\infty} (-1)^k \zeta(2k) z^{2k}, \quad (9)$$

computing the coefficients of z^{2k} , $k \leq n$, to sufficient accuracy, as mentioned in [3, 9, 10]. This is similar to the fast algorithm that we describe in §4. The similarity can be seen more clearly if we replace πz by z in (9), giving

$$\frac{z}{\tanh(z)} = -2 \sum_{k=0}^{\infty} (-1)^k \frac{\zeta(2k)}{\pi^{2k}} z^{2k}, \quad (10)$$

since it is the rational number $\zeta(2n)/\pi^{2n}$ that we need in order to compute B_{2n} from (5). In fact, it is easy to see that (10) is equivalent to (3).

There is a vast literature on Bernoulli, Tangent and Secant numbers. For example, the bibliography of Dilcher and Slavutskii [15] contains more than 2000 items. Thus, we do not attempt to give a complete list of references to related work. However, we briefly mention the problem of computing *irregular primes* [8, 11], which are odd primes p such that p divides the class number of the p -th cyclotomic field. The algorithms that we present in §§4–5 below are not suitable for this task because they take too much memory. It is much more space-efficient to use a modular algorithm where the computations are performed modulo a single prime (or maybe the product of a small number of primes), as in [8, 11, 14, 20]. Space can also be saved by the technique of “multisectioning”, which is described by Crandall [13, §3.2] and Hare [19].

3 Tangent and Secant Numbers

The *Tangent numbers* T_n ($n > 0$) (also called *Zag numbers*) are defined by

$$\sum_{n>0} T_n \frac{z^{2n-1}}{(2n-1)!} = \tan z = \frac{\sin z}{\cos z}.$$

Similarly, the *Secant numbers* S_n ($n \geq 0$) (also called *Euler* or *Zig numbers*) are defined by

$$\sum_{n \geq 0} S_n \frac{z^{2n}}{(2n)!} = \sec z = \frac{1}{\cos z}.$$

Unlike the Bernoulli numbers, the Tangent and Secant numbers are positive integers. Because $\tan z$ and $\sec z$ have poles at $z = \pi/2$, we expect T_n to grow roughly like $(2n-1)!(2/\pi)^n$ and S_n like $(2n)!(2/\pi)^n$. To obtain more precise estimates, let

$$\zeta_0(s) = (1 - 2^{-s})\zeta(s) = 1 + 3^{-s} + 5^{-s} + \dots$$

be the *odd zeta-function*. Then

$$\frac{T_n}{(2n-1)!} = \frac{2^{2n+1}\zeta_0(2n)}{\pi^{2n}} \sim \frac{2^{2n+1}}{\pi^{2n}} \quad (11)$$

(this can be proved in the same way as Euler's relation (5) for the Bernoulli numbers). We also have [1, (23.2.22)]

$$\frac{S_n}{(2n)!} = \frac{2^{2n+2}\beta(2n+1)}{\pi^{2n+1}} \sim \frac{2^{2n+2}}{\pi^{2n+1}}, \quad (12)$$

where

$$\beta(s) = \sum_{j=0}^{\infty} (-1)^j (2j+1)^{-s}. \quad (13)$$

From (5) and (11), we see that

$$T_n = (-1)^{n-1} 2^{2n} (2^{2n} - 1) \frac{B_{2n}}{2n}. \quad (14)$$

This can also be proved directly, without involving the zeta-function, by using the identity

$$\tan z = \frac{1}{\tan z} - \frac{2}{\tan(2z)}.$$

Since $T_n \in \mathbb{Z}$, it follows from (14) that the odd primes in the denominator of B_{2n} must divide $2^{2n} - 1$. This is compatible with the Von Staudt–Clausen theorem, since $(p-1)|2n$ implies $p|(2^{2n} - 1)$ by Fermat's little theorem.

T_n has about $4n$ more bits than $\lceil B_{2n} \rceil$, but both have $2n \lg n + O(n)$ bits, so asymptotically there is not much difference between the sizes of T_n and $\lceil B_{2n} \rceil$. Thus, if our

aim is to compute B_{2n} , we do not lose much by first computing T_n , and this may be more convenient since $T_n \in \mathbb{Z}$, $B_{2n} \in \mathbb{Q}$.

4 A Fast Algorithm for Bernoulli Numbers

Harvey [20] showed how B_n could be computed exactly, using a modular algorithm and the Chinese remainder theorem, in $O(n^2(\log n)^{2+o(1)})$ bit-operations. The same complexity can be obtained using (5) and the Euler product for the zeta-function (see the discussion in Harvey [20, §1]).

In this section we show how to compute *all* of B_0, \dots, B_n with almost the same complexity bound (only larger by a factor $O(\log n)$). In §5 we give an even faster algorithm, which avoids the $O(\log n)$ factor.

Let $A(z) = a_0 + a_1z + a_2z^2 + \dots$ be a power series with coefficients in \mathbb{R} , with $a_0 \neq 0$. Let $B(z) = b_0 + b_1z + \dots$ be the *reciprocal* power series, so $A(z)B(z) = 1$. Using the FFT, we can multiply polynomials of degree $n-1$ with $O(n \log n)$ real operations. Using Newton's method [24, 28], we can compute b_0, \dots, b_{n-1} with the *same* complexity $O(n \log n)$, up to a constant factor.

Taking $A(z) = (\exp(z) - 1)/z$ and working with N -bit floating-point numbers, where $N = n \lg(n) + O(n)$, we get B_0, \dots, B_n to sufficient accuracy to deduce the exact (rational) result. (Alternatively, use (3) to avoid computing the terms with odd subscripts, since these vanish except for B_1 .) The work involved is $O(n \log n)$ floating-point operations, each of which can be done with N -bit accuracy in $O(n(\log n)^{2+o(1)})$ bit-operations. Thus, overall we get B_0, \dots, B_n with $O(n^2(\log n)^{3+o(1)})$ bit-operations. Similarly for Secant and Tangent numbers. We omit a precise specification of N and a detailed error analysis of the algorithm, since it is improved in the following section.

5 A Faster Algorithm for Tangent and Bernoulli Numbers

To improve the algorithm of §4 for Bernoulli numbers, we use the “Kronecker–Schönhage trick” [7, §1.9]. Instead of working with power series $A(z)$ (or polynomials, which can be regarded as truncated power series), we work with binary numbers $A(z)$ where z is a suitable (negative) power of 2.

The idea is to compute a single real number \mathcal{A} which is defined in such a way that the numbers that we want to compute are encoded in the binary representation of \mathcal{A} . For example, consider the series

$$\sum_{k>0} k^2 z^k = \frac{z(1+z)}{(1-z)^3}, \quad |z| < 1.$$

The right-hand side is an easily-computed rational function of z , say $A(z)$. We use decimal rather than binary for expository purposes. With $z = 10^{-3}$ we easily find

$$A(10^{-3}) = \frac{1001000}{997002999} = 0.001004009016025036049064081100 \dots$$

Thus, if we are interested in the finite sequence of squares $(1^2, 2^2, 3^2, \dots, 10^2)$, it is sufficient to compute $\mathcal{A} = A(10^{-3})$ correctly rounded to 30 decimal places, and we can then “read off” the squares from the decimal representation of \mathcal{A} .

Of course, this example is purely for illustrative purposes, because it is easy to compute the sequence of squares directly. However, we use the same idea to compute Tangent numbers. Suppose we want the first n Tangent numbers (T_1, T_2, \dots, T_n) . The generating function

$$\tan z = \sum_{k \geq 1} T_k \frac{z^{2k-1}}{(2k-1)!}$$

gives us almost what we need, but not quite, because the coefficients are rationals, not integers. Instead, consider

$$(2n-1)! \tan z = \sum_{k=1}^n T'_{k,n} z^{2k-1} + R_n(z), \quad (15)$$

where

$$T'_{k,n} = \frac{(2n-1)!}{(2k-1)!} T_k \quad (16)$$

is an integer for $1 \leq k \leq n$, and

$$R_n(z) = \sum_{k=n+1}^{\infty} T'_{k,n} z^{2k-1} = (2n-1)! \sum_{k=n+1}^{\infty} T_k \frac{z^{2k-1}}{(2k-1)!} \quad (17)$$

is a remainder term which is small if z is sufficiently small. Thus, choosing $z = 2^{-p}$ with p sufficiently large, the first $2np$ binary places of $(2n-1)! \tan z$ define $T'_{1,n}, T'_{2,n}, \dots, T'_{n,n}$. Once we have computed $T'_{1,n}, T'_{2,n}, \dots, T'_{n,n}$ it is easy to deduce T_1, T_2, \dots, T_n from

$$T_k = \frac{T'_{k,n}}{(2n-1)!/(2k-1)!}.$$

For this idea to work, two conditions must be satisfied. First, we need

$$0 \leq T'_{k,n} < 1/z^2 = 2^{2p}, \quad 1 \leq k \leq n, \quad (18)$$

so we can read off the $T'_{k,n}$ from the binary representation of $(2n-1)! \tan z$. Since we have a good asymptotic estimate for T_k , it is not hard to choose p sufficiently large for this condition to hold.

Second, we need the remainder term $R_n(z)$ to be sufficiently small that it does not influence the estimation of $T'_{n,n}$. A sufficient condition is

$$0 \leq R_n(z) < z^{2n-1}. \quad (19)$$

Choosing z sufficiently small (i.e. p sufficiently large) guarantees that condition (19) holds, since $R_n(z)$ is $O(z^{2n+1})$ as $z \rightarrow 0$ with n fixed.

Lemmas 3 and 4 below give sufficient conditions for (18) and (19) to hold.

Lemma 1.

$$\frac{T_k}{(2k-1)!} \leq \left(\frac{2}{\pi}\right)^{2(k-1)} \text{ for } k \geq 1.$$

Proof. From (11),

$$\frac{T_k}{(2k-1)!} = 2 \left(\frac{2}{\pi}\right)^{2k} \zeta_0(2k) \leq 2 \left(\frac{2}{\pi}\right)^{2k} \zeta_0(2) \leq \left(\frac{2}{\pi}\right)^{2k} \frac{\pi^2}{4} = \left(\frac{2}{\pi}\right)^{2(k-1)} \quad \square$$

Lemma 2. $(2n-1)! \leq n^{2n-1}$ for $n \geq 1$.

Proof.

$$(2n-1)! = n \prod_{j=1}^{n-1} (n-j)(n+j) = n \prod_{j=1}^{n-1} (n^2 - j^2) \leq n^{2n-1}$$

with equality iff $n = 1$. \square

Lemma 3. If $k \geq 1$, $n \geq 2$, $p = \lceil n \lg(n) \rceil$, $z = 2^{-p}$, and $T'_{k,n}$ is as in (16), then $z \leq n^{-n}$ and $T'_{k,n} < 1/z^2$.

Proof. We have $z = 2^{-p} = 2^{-\lceil n \lg(n) \rceil} \leq 2^{-n \lg(n)} = n^{-n}$, which proves the first part of the Lemma.

Assume $k \geq 1$ and $n \geq 2$. From Lemma 1, we have

$$T'_{k,n} \leq (2n-1)! \left(\frac{2}{\pi}\right)^{2(k-1)} \leq (2n-1)!,$$

and from Lemma 2 it follows that

$$T'_{k,n} \leq n^{2n-1} < n^{2n}.$$

From the first part of the Lemma, $n^{2n} \leq 1/z^2$, so the second part follows. \square

Lemma 4. If $n \geq 2$, $p = \lceil n \lg(n) \rceil$, $z = 2^{-p}$, and $R_n(z)$ is as defined in (17), then $0 < R_n(z) < 0.1 z^{2n-1}$.

Proof. Since all the terms in the sum defining $R_n(z)$ are positive, it is immediate that $R_n(z) > 0$.

Since $n \geq 2$, we have $p \geq 2$ and $z \leq 1/4$. Now, using Lemma 1,

$$\begin{aligned}
 R_n(z) &= \sum_{k=n+1}^{\infty} T'_{k,n} z^{2k-1} \\
 &\leq (2n-1)! \sum_{k=n+1}^{\infty} \left(\frac{2}{\pi}\right)^{2(k-1)} z^{2k-1} \\
 &\leq (2n-1)! \left(\frac{2}{\pi}\right)^{2n} z^{2n+1} \left(1 + \left(\frac{2z}{\pi}\right)^2 + \left(\frac{2z}{\pi}\right)^4 + \dots\right) \\
 &\leq (2n-1)! \left(\frac{2}{\pi}\right)^{2n} z^{2n+1} \left/ \left(1 - \left(\frac{2z}{\pi}\right)^2\right) \right. .
 \end{aligned}$$

Since $z \leq 1/4$, we have $1/(1 - (2z/\pi)^2) < 1.026$. Also, from Lemma 2, $(2n-1)! \leq n^{2n-1}$. Thus, we have

$$\frac{R_n(z)}{z^{2n-1}} < 1.026 n^{2n-1} \left(\frac{2}{\pi}\right)^{2n} z^2.$$

Now $z^2 \leq n^{-2n}$ from the first part of Lemma 3, so

$$\frac{R_n(z)}{z^{2n-1}} < \frac{1.026}{n} \left(\frac{2}{\pi}\right)^{2n}. \quad (20)$$

The right-hand side is a monotonic decreasing function of n , so is bounded above by its value when $n = 2$, giving $R_n(z)/z^{2n-1} < 0.1$. \square

A high-level description of the resulting Algorithm FastTangentNumbers is given in Figure 1. The algorithm computes the Tangent numbers T_1, T_2, \dots, T_n using the Kronecker-Schönhage trick as described above, and deduces the Bernoulli numbers B_2, B_4, \dots, B_{2n} from the relation (14).

Input: integer $n \geq 2$

Output: Tangent numbers T_1, \dots, T_n and (optional) Bernoulli numbers B_2, B_4, \dots, B_{2n}

$p \leftarrow \lceil n \lg(n) \rceil$

$z \leftarrow 2^{-p}$

$S \leftarrow \sum_{0 \leq k < n} (-1)^k z^{2k+1} \times (2n)! / (2k+1)!$

$C \leftarrow \sum_{0 \leq k < n} (-1)^k z^{2k} \times (2n)! / (2k)!$

$V \leftarrow \lfloor z^{1-2n} \times (2n-1)! \times S/C \rfloor$ (here $\lfloor x \rfloor$ means round x to nearest integer)

Extract $T'_{k,n} = T_k(2n-1)! / (2k-1)!$, $1 \leq k \leq n$, from the binary representation of V

$T_k \leftarrow T'_{k,n} \times (2k-1)! / (2n-1)!$, $k = n, n-1, \dots, 1$

$B_{2k} \leftarrow (-1)^{k-1} (k \times T_k / 2^{2k-1}) / (2^{2k} - 1)$, $k = 1, 2, \dots, n$ (optional)

return T_1, T_2, \dots, T_n and (optional) B_2, B_4, \dots, B_{2n}

Fig. 1 Algorithm FastTangentNumbers (also optionally computes Bernoulli numbers)

In order to achieve the best complexity, the algorithm must be implemented carefully using binary arithmetic. The computations of S (an approximation to $(2n)!\sin z$) and C (an approximation to $(2n)!\cos z$) involve computing ratios of factorials such as $(2n)!/(2k)!$, where $0 \leq k \leq n$. This can be done in time $O(n^2(\log n)^2)$ by a straightforward algorithm. The N -bit division to compute S/C (an approximation to $\tan z$) can be done in time $O(N \log(N) \log \log(N))$ by the Schönhage–Strassen algorithm combined with Newton’s method [7, §4.2.2]. Here it is sufficient to take $N = 2np + 2 = 2n^2 \lg(n) + O(n)$. Note that

$$V = \sum_{k=1}^n 2^{2(n-k)p} T'_{k,n} \quad (21)$$

is just the finite sum in (15) scaled by z^{1-2n} (a power of two), and the integers $T'_{k,n}$ can simply be “read off” from the binary representation of V in n blocks of $2p$ consecutive bits. The $T'_{k,n}$ can then be scaled by ratios of factorials in time $O(n^2(\log n)^{2+o(1)})$ to give the Tangent numbers T_1, T_2, \dots, T_n .

The correctness of the computed Tangent numbers follows from Lemmas 3–4, apart from possible errors introduced by S/C being only an approximation to $\tan(z)$. Lemma 5 shows that this error is sufficiently small.

Lemma 5. *Suppose that $n \geq 2$, z , S and C as in Algorithm FastTangentNumbers. Then*

$$z^{1-2n}(2n-1)! \left| \frac{S}{C} - \tan z \right| < 0.02. \quad (22)$$

Proof. We use the inequality

$$\left| \frac{A}{B} - \frac{A'}{B'} \right| \leq \frac{|A| \cdot |B - B'| + |B| \cdot |A - A'|}{|B| \cdot |B'|}. \quad (23)$$

Take $A = \sin z$, $B = \cos z$, $A' = S/(2n)!$, $B' = C/(2n)!$ in (23). Since $n \geq 2$ we have $0 < z \leq 1/4$. Then $|A| = |\sin z| < z$. Also, $|B| = |\cos z| > 31/32$ from the Taylor series $\cos z = 1 - z^2/2 + \dots$, which has terms of alternating sign and decreasing magnitude. By similar arguments, $|B'| \geq 31/32$, $|B - B'| < z^{2n}/(2n)!$, and $|A - A'| < z^{2n+1}/(2n+1)!$. Combining these inequalities and using (23), we obtain

$$\left| \frac{S}{C} - \tan z \right| < \frac{6 \cdot 32 \cdot 32 \cdot z^{2n+1}}{5 \cdot 31 \cdot 31 \cdot (2n)!} < \frac{1.28 z^{2n+1}}{(2n)!}.$$

Multiplying both sides by $z^{1-2n}(2n-1)!$ and using $1.28 z^2/(2n) \leq 0.02$, we obtain the inequality (22). This completes the proof of Lemma 5. \square

In view of the constant 0.02 in (22) and the constant 0.1 in Lemma 4, the effect of all sources of error in computing $z^{1-2n}(2n-1)!\tan z$ is at most $0.12 < 1/2$, which is

too small to change the computed integer V , that is to say, the computed V is indeed given by (21).

The computation of the Bernoulli numbers B_2, B_4, \dots, B_{2n} from T_1, \dots, T_n , is straightforward (details depending on exactly how rational numbers are to be represented). The entire computation takes time

$$O(N(\log N)^{1+o(1)}) = O(n^2(\log n)^{2+o(1)}).$$

Thus, we have proved:

Theorem 1. *The Tangent numbers T_1, \dots, T_n and Bernoulli numbers B_2, B_4, \dots, B_{2n} can be computed in $O(n^2(\log n)^{2+o(1)})$ bit-operations using $O(n^2 \log n)$ space.*

A small modification of the above can be used to compute the Secant numbers S_0, S_1, \dots, S_n in $O(n^2(\log n)^{2+o(1)})$ bit-operations and $O(n^2 \log n)$ space. The bound on Tangent numbers given by Lemma 1 can be replaced by the bound

$$\frac{S_n}{(2n)!} \leq 2 \left(\frac{2}{\pi} \right)^{2n+1}$$

which follows from (12) since $\beta(2n+1) < 1$.

We remark that an efficient implementation of Algorithm FastTangentNumbers in a high-level language such as Sage [32] or Magma [5] is nontrivial, because it requires access to the internal binary representation of high-precision integers. Everything can be done using (implicitly scaled) integer arithmetic – there is no need for floating-point – but for the sake of clarity we did not include the scaling in Figure 1. If floating-point arithmetic is used, a precision of N bits is sufficient, where $N = 2np + 2$.

Comparing our Algorithm FastTangentNumbers with Harvey’s modular algorithm [20], we see that there is a space-time trade-off: Harvey’s algorithm uses less space (by a factor of order n) to compute a single B_n , but more time (again by a factor of order n) to compute all of B_1, \dots, B_n . Harvey’s algorithm has better locality and is readily parallelisable.

In the following section we give much simpler algorithms which are fast enough for most practical purposes, and are based on three-term recurrence relations.

6 Algorithms Based On Three-Term Recurrences

Akiyama and Tanigawa [21] gave an algorithm for computing Bernoulli numbers based on a three-term recurrence. However, it is only useful for exact computations, since it is numerically unstable if applied using floating-point arithmetic. It is faster to use a stable recurrence for computing Tangent numbers, and then deduce the Bernoulli numbers from (14).

6.1 Bernoulli and Tangent numbers

We now give a stable three-term recurrence and corresponding in-place algorithm for computing Tangent numbers. The algorithm is perfectly stable since all operations are on positive integers and there is no cancellation. Also, it involves less arithmetic than the Akiyama-Tanigawa algorithm. This is partly because the operations are on integers rather than rationals, and partly because there are fewer operations since we take advantage of zeros.

Bernoulli numbers can be computed using Algorithm TangentNumbers and the relation (14). The time required for the application of (14) is negligible.

The recurrence (24) that we use was given by Buckholtz and Knuth [23], but they did not give our in-place Algorithm TangentNumbers explicitly. Related recurrences with applications to parallel computation were considered by Hare [19].

Write $t = \tan x$, $D = d/dx$, so $Dt = 1 + t^2$ and $D(t^n) = nt^{n-1}(1 + t^2)$ for $n \geq 1$. It is clear that $D^n t$ is a polynomial in t , say $P_n(t)$. Write $P_n(t) = \sum_{j \geq 0} p_{n,j} t^j$. Then $\deg(P_n) = n + 1$ and, from the formula for $D(t^n)$,

$$p_{n,j} = (j - 1)p_{n-1,j-1} + (j + 1)p_{n-1,j+1}. \quad (24)$$

We are interested in $T_k = (d/dx)^{2k-1} \tan x|_{x=0} = P_{2k-1}(0) = p_{2k-1,0}$, which can be computed from the recurrence (24) in $O(k^2)$ operations using the obvious boundary conditions. We save work by noticing that $p_{n,j} = 0$ if $n + j$ is even. The resulting algorithm is given in Figure 2.

```

Input: positive integer  $n$ 
Output: Tangent numbers  $T_1, \dots, T_n$ 
 $T_1 \leftarrow 1$ 
for  $k$  from 2 to  $n$ 
     $T_k \leftarrow (k - 1)T_{k-1}$ 
for  $j$  from  $k$  to  $n$ 
     $T_j \leftarrow (j - k)T_{j-1} + (j - k + 2)T_j$ 
return  $T_1, T_2, \dots, T_n$ .

```

Fig. 2 Algorithm TangentNumbers

The first **for** loop initializes $T_k = p_{k-1,k} = (k - 1)!$. The variable T_k is then used to store $p_{k,k-1}, p_{k+1,k-2}, \dots, p_{2k-2,1}, p_{2k-1,0}$ at successive iterations of the second **for** loop. Thus, when the algorithm terminates, $T_k = p_{2k-1,0}$, as expected.

The process in the case $n = 3$ is illustrated in Figure 3, where $T_k^{(m)}$ denotes the value of the variable T_k at successive iterations $m = 1, 2, \dots, n$. It is instructive to compare a similar Figure for the Akiyama-Tanigawa algorithm in [21].

Algorithm TangentNumbers takes $\Theta(n^2)$ operations on positive integers. The integers T_n have $O(n \log n)$ bits, other integers have $O(\log n)$ bits. Thus, the overall

Fig. 3 Dataflow in Algorithm TangentNumbers for $n = 3$

complexity is $O(n^3(\log n)^{1+o(1)})$ bit-operations, or $O(n^3 \log n)$ word-operations if n fits in a single word.

The algorithm is not optimal, but it is good in practice for moderate values of n , and much simpler than asymptotically faster algorithms such as those described in §§4–5. For example, using a straightforward Magma implementation of Algorithm TangentNumbers, we computed the first 1000 Tangent numbers in 1.50 sec on a 2.26 GHz Intel Core 2 Duo. For comparison, it takes 1.92 sec for a single N -bit division computing T in Algorithm FastTangentNumbers (where $N = 19931568$ corresponds to $n = 1000$). Thus, we expect the crossover point where Algorithm FastTangentNumbers actually becomes faster to be slightly larger than $n = 1000$ (but dependent on implementation details).

6.2 Secant numbers

A similar algorithm may be used to compute Secant numbers. Let $s = \sec x$, $t = \tan x$, and $D = d/dx$. Then $Ds = st$, $D^2s = s(1 + 2t^2)$, and in general $D^n s = sQ_n(t)$, where $Q_n(t)$ is a polynomial of degree n in t . The Secant numbers are given by $S_k = Q_{2k}(0)$. Let $Q_n(t) = \sum_{k \geq 0} q_{n,k} t^k$. From

$$D(st^k) = st^{k+1} + kst^{k-1}(1 + t^2)$$

we obtain the three-term recurrence

$$q_{n+1,k} = kq_{n,k-1} + (k+1)q_{n,k+1} \quad \text{for } 1 \leq k \leq n. \quad (25)$$

By avoiding the computation of terms $q_{n,k}$ that are known to be zero ($n+k$ odd), and ordering the computation in a manner analogous to that used for Algorithm TangentNumbers, we obtain Algorithm SecantNumbers (see Figure 4), which computes the Secant numbers in place using non-negative integer arithmetic.

```

Input: positive integer  $n$ 
Output: Secant numbers  $S_0, S_1, \dots, S_n$ 
 $S_0 \leftarrow 1$ 
for  $k$  from 1 to  $n$ 
     $S_k \leftarrow kS_{k-1}$ 
for  $k$  from 1 to  $n$ 
    for  $j$  from  $k+1$  to  $n$ 
         $S_j \leftarrow (j-k)S_{j-1} + (j-k+1)S_j$ 
return  $S_0, S_1, \dots, S_n$ .

```

Fig. 4 Algorithm SecantNumbers

6.3 Comparison with Atkinson's algorithm

Atkinson [2] gave an elegant algorithm for computing both the Tangent numbers T_1, T_2, \dots, T_n and the Secant numbers S_0, S_1, \dots, S_n using a “Pascal's triangle” style of algorithm that only involves additions of non-negative integers. Since a triangle with $2n+1$ rows is involved, Atkinson's algorithm requires $2n^2 + O(n)$ integer additions. This can be compared with $n^2/2 + O(n)$ additions and $n^2 + O(n)$ multiplications (by small integers) for our Algorithm TangentNumbers, and similarly for Algorithm SecantNumbers.

Thus, we might expect Atkinson's algorithm to be slower than Algorithm TangentNumbers. Computational experiments confirm this. With $n = 1000$, Algorithm TangentNumbers programmed in Magma takes 1.50 seconds on a 2.26 GHz Intel Core 2 Duo, algorithm SecantNumbers also takes 1.50 seconds, and Atkinson's algorithm takes 4.51 seconds. Thus, even if both Tangent and Secant numbers are required, Atkinson's algorithm is slightly slower. It also requires about twice as much memory.

Acknowledgements We thank Jon Borwein for encouraging the belief that high-precision computations are useful in “experimental” mathematics [4], e.g. in the PSLQ algorithm [16]. Ben F. “Tex” Logan, Jr. [25] suggested the use of Tangent numbers to compute Bernoulli numbers. Christian Reinsch [26] pointed out the numerical instability of the recurrence (7) and suggested the use of the numerically stable recurrence (8). Christopher Heckman kindly drew our attention to Atkinson's algorithm [2]. We thank Paul Zimmermann for his comments. Some of the material presented here is drawn from the recent book *Modern Computer Arithmetic* [7] (and as-yet-unpublished solutions to exercises in the book). In particular, see [7, §4.7.2 and exercises 4.35–4.41]. Finally, we thank David Bailey, Richard Crandall, and two anonymous referees for suggestions and pointers to additional references.
